

PROPERTY TAX SALES, PRIVATE CAPITAL,  
AND GENTRIFICATION IN THE U.S.

Cameron LaPoint

March 13th, 2024

## PROPERTY TAX SYSTEM AND DISTRESSED HOUSING MARKETS ARE LINKED

- Local govts. in U.S. rely on property tax revenues to fund public goods and services
- Govt. has **recourse** and places super senior lien on delinquent properties
  - ▶ Real property implicitly serves as collateral for tax debt in most regimes worldwide
- **Tax sales:** forced sales resulting from severely delinquent local taxes
  - ▶ Other types of forced sales: mortgage foreclosure, estate, and bankruptcy auctions
- Tax authority charges interest, sends reminders to property owner, and finally sells claims to investors at (semi-)annual auctions to recoup lost revenues
  - ▶ Surplus revenues generated by auction but still sold for pennies on dollar
  - ▶ Entity who redeems the debt has low-cost opportunity to acquire property
  - ▶  $\implies$  **opportunistic developers** enter new neighborhoods

Tax bill overdue as of  
October 1st, 2021.  
**Average unredeemed  
tax debt = \$3,700.**

Debt redeemed before July 19th, 2022 tax lien auction.

Tax bill overdue as of October 1st, 2021.

**Average unredeemed tax debt = \$3,700.**

Debt redeemed before July 19th, 2022 tax lien auction.

Property lien sold at annual auction.  
**Average final bid = \$17,400.**

No one bids, so sold at OTC sale at later date.

Tax bill overdue as of October 1st, 2021.  
**Average unredeemed tax debt = \$3,700.**

Debt redeemed before July 19th, 2022 tax lien auction.

Property lien sold at annual auction.  
**Average final bid = \$17,400.**

No one bids, so sold at OTC sale at later date.

Tax bill overdue as of October 1st, 2021.  
**Average unredeemed tax debt = \$3,700.**

Debt redeemed by interested party during 6-month redemption period.

Debt redeemed before July 19th, 2022 tax lien auction.

Property lien sold at annual auction. Average final bid = \$17,400.

Tax bill overdue as of October 1st, 2021. Average unredeemed tax debt = \$3,700.

New lien sold at next auction if investor does not foreclose.

No one bids, so sold at OTC sale at later date.

Investor holds lien to maturity and forecloses (11% of liens). Average assessed market value = \$578,100.

Debt redeemed by interested party during 6-month redemption period.

Debt redeemed before July 19th, 2022 tax lien auction.

Property lien sold at annual auction.  
Average final bid = \$17,400.

Tax bill overdue as of October 1st, 2021.  
Average unredeemed tax debt = \$3,700.

New lien sold at next auction if investor does not foreclose.

No one bids, so sold at OTC sale at later date.

Investor holds lien to maturity and forecloses (11% of liens).  
Average assessed market value = \$578,100.

Debt redeemed by interested party during 6-month redemption period.

Debt redeemed before July 19th, 2022 tax lien auction.

Property lien sold at annual auction.  
**Average final bid = \$17,400.**

Tax bill overdue as of October 1st, 2021.  
**Average unredeemed tax debt = \$3,700.**

New lien sold at next auction if investor does not foreclose.

No one bids, so sold at OTC sale at later date.

Investor holds lien to maturity and forecloses (11% of liens).  
**Average assessed market value = \$578,100.**

Debt redeemed by interested party during 6-month redemption period.

Interest (1.5% monthly) + one-time penalty (10%) accrues.

Interest and penalties stop accruing once redeemed by taxpayer or by title transfer.

## TIMELINE OF TAX SALES BY THE NUMBERS

- Data from Washington, D.C. (real 2012 \$), but representative of lien auction format
- Unlike most types of mortgage foreclosure and bankruptcy, **equity gets forfeited**
  - ▶ In many states, taxpayer has no clear legal claim to exceed proceeds at auction!
- Implied haircut is much larger than the 20-25% at mortgage foreclosure auctions
  - ▶ Look at non-repeat delinquency, arms-length, non-REO title transfers
  - ▶ Scale market value of property by observed 11% arms-length tax foreclosure prob.
  - ▶  $\implies \mathbb{E}[V]/\text{bid} = 11\% \text{ prob.} \times (\$578,100/\$17,400) \approx \mathbf{3.5 \text{ times auction price!}}$
  - ▶ If restrict to only court foreclosures ( $< 1/3$ ), then 3% prob.  $\implies$  approx. actuarially fair
- **Underpricing** of tax foreclosure options **amplifies** property development relative to what might occur via mortgage foreclosures Option pricing

# ≈ 2.2% OF TAXABLE PROPERTIES BECOME DELINQUENT EACH YEAR

Property tax delinquency rate = # of liens per taxable residence

Notes: Tabulated using merged CoreLogic Involuntary Liens and Tax data for 2008 – 2014.

- Represents 2.3 million taxable residences each year [Map w/state FEs](#)
- Some states have much higher rates due to “revolving” liens (e.g. FL, GA)

# MOTIVATION: CONCERNS ABOUT AFFORDABILITY WITHIN BOOMING MARKETS

**Source:** *Washington Post*, "Pushed out," September 21, 2019. Figure shows how two blocks on 13th St. NW in Washington, D.C. became steadily redeveloped over the last twenty years.

# THIS PAPER: GENTRIFICATION THROUGH CHEAP FORECLOSURE OPTIONS

- Tax sale investment acts as a vehicle for neighborhood demographic change
  - ① **Characterize strategies of banks, taxpayers, and investors**
    - ★ Intermediaries sell foreclosure options on secondary market to large private funds
  - ② **Reduced-form model of population flows to tag gentrifying areas**
    - ★ Application: show investors target tax liens in gentrifying areas D.C. Baltimore Indy Detroit
  - ③ **Use state-of-art spatial DiD methods to document local pricing spillover effects**
    - ★ On average, values of neighboring homes 2-3% ↓ after tax sale
    - ★ Heterogeneity: due to redevelopment, in gentrifying areas prices 10% ↑ within 3 years
  - ④ **Document demographic changes resulting from tax sales**
    - ★ Gentrification: new homebuyers 2 p.p. less likely to be underrepresented minorities [URMs] after nearby tax sale to institutional investors (relative to baseline 12% URM buyer prob.)

# NEW STYLIZED FACTS ABOUT TAX SALE MARKETS

- Little prior quantitative work on tax sales
  - ▶ Whitaker & Fitzpatrick (2013) on Chicago; Alm et al. (2016) on Cleveland
  - ▶ Large sociology literature on abandonment in Detroit (e.g. Akers & Seymour 2019)
- Property tax regressivity might contribute to delinquency outcomes
  - ▶ Hodge et al. (2017); Berry (2018, 2021); McMillen & Singh (2020); Amornsiripanitch (2023)
- This paper: who is buying the tax claims, how, and why?
  - ① Who? A small handful of investors acting as **intermediaries**
  - ② How? Bidding for tax liens on properties **without a mortgage lien**
  - ③ Why? Relatively cheap redevelopment option in high CoL areas and high statutorily **guaranteed yield** on lien even without moving to foreclose

## OTHER RELATED WORK

### ● **Knock-on effects of distressed/affordable housing development**

- ▶ Distressed sales: Campbell, Giglio, Pathak (2011); Anenberg & Kung (2014); Gerardi et al. (2015); Favara & Giannetti (2017); Gupta (2019); [Ganduri & Maturana \(2022\)](#)
- ▶ Affordable housing: Autor, Palmer, Pathak (2014); [Diamond & McQuade \(2019\)](#), Asquith, Mast, Reed (2019); Boustan et al. (2019); Pennington (2021); Soltas (2022)

### ● **Corporate retail & “institutional” real estate investors**

### ● **Racial disparities in homeownership**

- ▶ Brookings (2018); Kahn (2021); [Kermani & Wong \(2021\)](#); Bayer, Charles, Park (2021); [Avenancio-León & Howard \(2022\)](#); Zhang (2022); Gupta, Hansman, Mabile (2023)

### ● **Empirically identifying gentrification**

- ▶ [Brueckner & Rosenthal \(2009\)](#); Guerrieri, Hartley, Hurst (2013); Glaeser, Kim, Luca (2018); Couture & Handbury (2019); Baum-Snow & Hartley (2020); Ding & Hwang (2020)

## OTHER RELATED WORK

- Knock-on effects of distressed/affordable housing development
- Corporate retail & “institutional” real estate investors
- Racial disparities in homeownership
- Empirically identifying gentrification patterns

**Beyond new tax sale database, my contribution is to...**

**Establish links between distressed sales → intermediaries → developers, and how investors' strategies drive neighborhood change within municipal finance system.**

## LEGAL & INSTITUTIONAL BACKGROUND

## PROPERTY TAX DELINQUENCY: BASIC PRINCIPLES

- By default, lien placed on property once a local tax obligation is delinquent
  - ▶ *In rem* instead of *in personam* taxation
  - ▶  $\implies$  **debt follows property**, so cannot be discharged via bankruptcy
  - ▶  $\implies$  not dominated by federal tax lien, so IRS has to buy out the lienholder
- Suppose property tax bill becomes overdue...
  - ▶ Household then begins to receive delinquency notices and penalties/interest accrue
  - ▶ Final notice to taxpayer usually sent 2-4 weeks before an annual tax sale event
  - ▶ **If not paid by final due date, lien or deed sold to investors to recover revenue**
  - ▶ Generally, same process for other local liens (e.g. sanitation or “weed” liens)

Washington, D.C. 20024

Notice Number: 0712082190501

### REAL PROPERTY TAX BILL

| Square       | Suffix | Lot  | Property Address | Mrtg. No. | Assessment                          | Tax Rate/\$100 | Annual Tax        |
|--------------|--------|------|------------------|-----------|-------------------------------------|----------------|-------------------|
| 3310         |        | 0102 | 4306 3RD ST NW   |           | \$525,650                           | 0.85           | \$4,468.02        |
| DESCRIPTION  |        |      | TAX              | PENALTY   | INTEREST                            | PAYMENT        | TOTAL             |
| 2018         |        |      | \$4,309.16       | \$430.92  | \$711.01                            |                | \$5,451.09        |
| <b>Total</b> |        |      |                  |           | <b>Payment due by May 31, 2019:</b> |                | <b>\$5,451.09</b> |

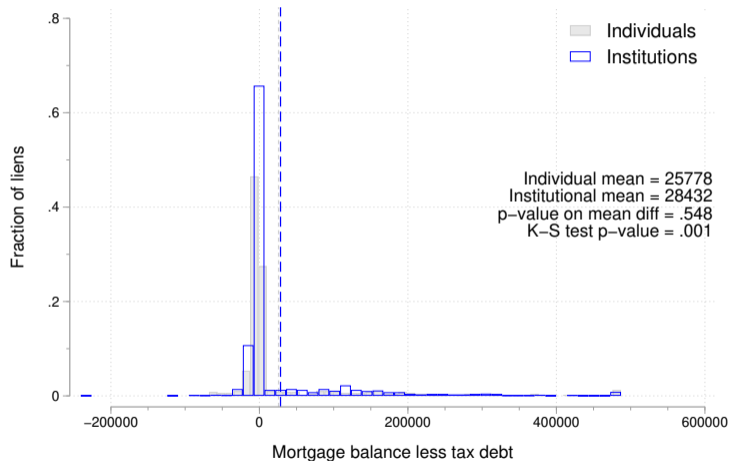

- In D.C., statutory 10% penalty rate + 18% annualized interest on the tax bill

## HOW IS THIS RELATED TO MORTGAGE FORECLOSURES?

- Short answer: mortgage foreclosures & tax sales are (nearly) **disjoint** events
  - ▶ 0.9% of tax liens result in a mortgage foreclosure in merged CoreLogic/tax sale sample
  - ▶ Compared to 4.1% foreclosure rate for all CoreLogic title exchanges
- Banks w/capital stake in property would step in to redeem **super senior** tax debt
  - ▶ Due process considerations require that lenders be notified of delinquency (Alexander 2000)
- **On the taxpayer side:** most lenders require **escrow** account with monthly payments used to cover local tax bill
  - ▶ HOs w/long tenure less likely to have escrow accounts, so payment not automatic
  - ▶ Potential elderly incapacitation channel (Moulton et al. 2022 *NTJ*) ADRD
  - ▶ Even within tract category, foreclosed properties further from elderly care sites
  - ▶ Result is price haircuts well below a mortgage foreclosure

# MOST LENDERS HAVE NO MONEY ON TABLE BY AUCTION DATE

- 54.8% of tax sale properties have no mortgage for last transaction prior to auction
- Of remaining 45.2%, 5.1 p.p. have a loan with term ending before the auction
- For remaining properties, use **30-year amortization schedule**
- $\leq \$0$  or  $\approx \$0 \implies$  not profitable for lender to redeem the tax lien

Amortization

FRMs

## WHY WOULDN'T A LENDER STEP IN TO REDEEM DEBT?

- **Answer:  $\approx$  70% of tax sale properties are owned outright** Algo

- ▶ Escrow puts tax payments on autopilot
- ▶ Also means more equity at stake if eventual foreclosure event

- Why do some lenders have skin in the game but not foreclose?
  - 1 Homeowner (or other interested party) pays off their debt after the auction
  - 2 Lender pays off debt and then works with the homeowner to restructure their mortgage repayment schedule

## CASE STUDY: WASHINGTON, D.C. TAX LIEN MARKET

## WHY IS D.C. A GOOD MARKET TO STUDY?

- Main reason: detailed auction records merged with CoreLogic and Zillow, but also...
  - ▶ Major RE market with high CoL Baltimore Indianapolis Detroit Ledger
    - ★ \$240 bil. housing stock, or #11 ranked city globally (CBRE 2017)
  - ▶ City is heavily reliant on property tax revenues
    - ★ 32% of local tax revenues compared to 3% national average (FY 2019 Census ASSLGF)
  - ▶ Auction system follows majority of U.S. jurisdictions
- **In progress:** expand the analysis to all major metros w/records Details
  - ▶ Tax sales not systematically recorded in standard datasets → **create new database**
  - ▶ ZTRAX has auction flag, CoreLogic Involuntary Liens records just the lien event
  - ▶ Otherwise, rely on scraping, FOIA requests, geocoding tools → **300k liens collected**

**Surplus** = bid amount – (back taxes + interest + penalties owed)

# SURPLUS BIDS AT D.C. AUCTION NOT GIVEN BACK TO HOMEOWNER

$$\text{Surplus} = \text{bid amount} - (\text{back taxes} + \text{interest} + \text{penalties owed})$$

- Surplus is 63% of auction revenues
- 2020 auction cancelled due to COVID

- Surplus is zero for OTC sales
  - ▶ “Take it or leave it” offers
- In most cases investors bid more than the tax debt (surplus > 0)
- Surplus value does not go back to the homeowner or lender!
  - ▶ Investor gets surplus back once debt is eventually paid off or cancelled
- Gap between tax debt and subsequent sale prices is not rebated back to HO
- Subsequent foreclosure results in **home equity forfeiture**

## BIDDING STRATEGIES VARY BY INVESTOR TYPE

- Classify auction bidders into three types using keyword strings:
  - ① **Investors:** e.g. “LLC”, “FUND”, “INC”, “BANK”, “REALTY”, “PARTNERS”, “CAPITAL”, “TRUST”, “CORPORATION”, “PLLC” (Lambie-Hanson, Li, Slonkosky 2022)
  - ② **Non-profits:** e.g. “PRAYER”, “CHURCH”, “COMMUNITY”, “FAITH”, “UNIVERSITY”, “COLLEGE”, “SCHOOL”, “BAPTIST”, “FOUNDATION”, “GOVERNMENT”, “EMBASSY”, “CENTER”, “COOPERATIVE”, “FRIENDSHIP”, “MINISTRIES”, “FEDERAL”, “REHABILITATION”
  - ③ **Individuals:** lienholders with (first name, surname) format + not containing keywords in above two lists
- In D.C. tax lien auctions, retail/institutional investors...
  - ▶ Purchase liens on more valuable properties in gentrifying areas Maps Distribution
  - ▶ Obtain higher **“foreclosure yields”** (lower bid-to-value) Distribution
  - ▶ Are more likely to bid in contested auctions Price index

# BID-TO-VALUE (“FORECLOSURE YIELD”) BY INVESTOR TYPE

Overall bid to assessment ratio

Individuals

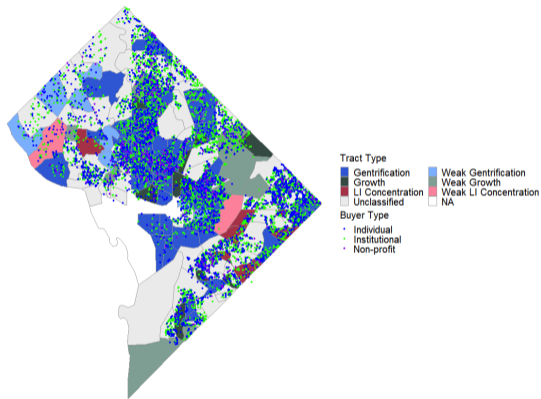

Institutions

# INVESTORS MORE LIKELY TO BUY IN GENTRIFYING D.C. AREAS

A. Using 1990-2005 tract definitions

B. Using 2005-2019 tract definitions

- Excluding sales to non-profit buyers, 72% of all sales within initially gentrifying tracts were to institutional investors (57% before Lehman crash)

[Crosstabs](#)

[Intro](#)

[Definition](#)

- **Who ultimately owns properties sold at tax auction?**
- Several challenges in answering this question:
  - ▶ Acquiring properties through tax foreclosure generates **social opprobrium**
  - ▶ Bidders need only provide an SSN/EIN, name, and address to bid
  - ▶ **Strategic tax defaults to preserve anonymity:** “repeat delinquency” events involving quick transfers between shell LLCs which appear in sample only once
- **Some defaulted properties can be linked to subsequent private equity deals**
  - ▶ Merge set of currently held properties to single-asset RE deals in Preqin → 696 deals spanning 493 unique addresses in D.C., 2000-19
  - ▶ Hand-match to auction roster → 19 residential + 24 mixed-use properties (59 deals)
  - ▶ Total PE deal value involving tax sale assets > \$5 billion (matched sample)

## PERE BINGO: BUYERS AND SELLERS IN POST-TAX SALE ASSET DEALS

wellsrealestatefunds blackrock  
o'connorcapitalpartners

- 26 of the 59 matched deals originate from “unidentified seller(s),” but some big names
- Intermediaries who buy at auction instead have amorphous names like HEARTWOOD 20 LLC, CAPITOL TAX SERVICES LLC, TIDEWATER ASSETS LLC, etc.

# CLEAR RACIAL DISPARITIES IN INCIDENCE OF TAX DELINQUENCY

- Severe delinquency 2 p.p. more likely among Black homeowners (HOs)  $\implies$  33% higher incidence than overall Black share of HOs
- Hispanics 27%, Asians 20% less likely to be delinquent than their HO share
- Method: Bayes's rule with Census common surnames list and voter registration [Details](#) [Robustness](#)
- **Disparate impact** from regressive assessments (Avenancio-León & Howard 2022)

# LOCAL SPILLOVER EFFECTS OF TAX LIENS ON HOUSE PRICES

## KEY EMPIRICAL CHALLENGES IN THIS CONTEXT

- Location of tax sales is endogenous to outcomes of interest
  - ▶ Owners more likely to become delinquent in struggling neighborhoods
  - ▶ Investors more likely to purchase in areas with higher expected returns
- Typical solution: control for **“very local”** time trends
- The timing of tax sales is also endogenous to counterparty decisions
  - ▶ Depends on whether tax authority can find a buyer (special OTC sales)
  - ▶ Owners may “strategically default” when redemption cost is low (O’Flaherty 1990)
- Possible solution on timing side: in national cross-section use differential pass-through of shocks to municipal budgets (reforms uncommon)
  - ▶ Weak second stage: state govt. redistributes across munis

# METHODS FOR ISOLATING TAX SALE SPILLOVERS

- Compare several existing approaches in the literature:
  - ① Ring DiD: compare outcomes in inner ring to those in outer ring around sale event M1
  - ② Foreclosure wave regressions à la Campbell, Giglio, Pathak (2011) M2 Bulk buying
  - ③ **Empirical derivatives estimator** (Diamond & McQuade 2019): semi-parametric ring DiD by tracing out slope of conditional mean w.r.t. distance M3
- Problem: need to guess “correct” radius to identify treatment effects
  - ▶ Parallel trends has to hold at every distance in the outer ring (Butts 2021)
  - ▶ Overlapping rings here makes it tricky to define distance running variable
- **Alternative solutions:** define control group using something other than distance
  - ▶ Identify delinquent properties which were redeemed right before auction
  - ▶ ML methods to identify counterfactual tax lien sale locations (Pollmann 2021)

## STANDARD METHOD: FORECLOSURE WAVE REGRESSIONS

- Parametric version of ring analysis via POLS where include geography  $\times$  time FEs, controls  $\mathbf{X}_{i,t}$  for property characteristics:

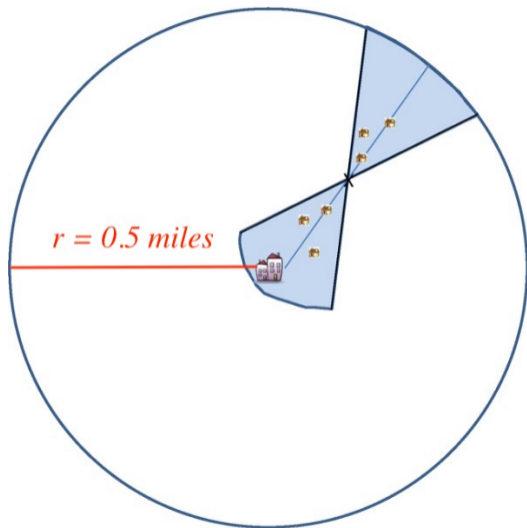

$$\begin{aligned} \log(p_{i,c,t}) = & \alpha_{c,t} + \gamma_m + \beta' \cdot \mathbf{X}_{i,t} + \delta_{C,B} \cdot g(N_{C,B}; D_{C,B}) \\ & + \delta_{C,A} \cdot g(N_{C,A}; D_{C,A}) + \delta_{F,B} \cdot h(N_{F,B}) + \delta_{F,A} \cdot h(N_{F,A}) + \varepsilon_{i,c,t} \end{aligned} \quad (1)$$

- ▶  $g(\cdot)$ : distance-weighted sum of tax sales where the weight is  $\omega = \frac{0.1 - D(i)}{0.1}$
  - ▶  $h(\cdot)$ : unweighted sum of tax sales
  - ▶  $\{B, A\}$  subscripts indicate before (B) vs. after (A) tax sale event
  - ▶  $\{C, F\}$  subscripts indicate whether  $i$  is “close” ( $r < 0.1$  mi.) or “far” ( $r < 0.25$  mi.)
- Key estimate of interest:  $\widehat{\delta}_{C,B} - \widehat{\delta}_{C,A}$  captures how one additional tax sale transfer influences values of nearby properties

|   | (1)                  | (2)                  | (3)                  | (4)                  |

| N   | 100,504              | 100,504              | 66,461               | 66,461               |
| Adj. $R^2$                                  | 0.427                | 0.452                | 0.708                | 0.771                |

- On average, (-) pricing spillover of 2-3%
  - ▶ Small spillover at “far” distance
- But (+) in areas with many, but not too many, tax sales
  - ▶ “Bulk buy” strategy of institutional investors (Ganduri, Xiao, Xiao 2022)
- Tax sales more common and geographically clustered than mtg. foreclosures or bankruptcy Mortgage table
  - ▶ 99.9th percentile to the maximum is 64.12–94.11 tax sales
- Can  $\approx$  match  $(\hat{\delta}_{C,B} - \hat{\delta}_{C,A})$  in mtg. foreclosure literature if I use exact same set of controls/sampling

## METHOD #3 (ILLUSTRATION): THE “BOWTIE” IN THE ED METHOD

- Idea: account for very local time trends by tracing out how outcomes **continuously** evolve w.r.t. time/distance to event
  - ▶ Compare property pairs  $\pm\delta$  away in Polar coordinate plane for fixed  $\theta$
- **Event:** house in the center is a tax sale property transferred to investor after redemption period ends
- **Semi-parametric:** pick **ring radius** and “smoothing” parameters to determine size of shaded area

Robustness

$\Delta P \gg 0$  IN UP-AND-COMING AREAS AFTER TAX SALES TO INVESTORS

### Sales in recently gentrifying tracts

- Focus on arms-length transfers to investors after tax auction
- ED method produces flat price surface prior to foreclosure event
- Sales prices 10%↑ at close distances within 5 years
- Price differences decay towards zero around 0.5 miles away → set  $r = 0.5$  mi. Inner ring
- Similar effects whether define event as foreclosure sale to LLC vs. non-LLC investor Individuals

# HETEROGENEOUS EFFECTS BY NEIGHBORHOOD TYPE

A. Sales in previously gentrifying tracts

B. Sales in previously non-gentrifying tracts

C. Sales in recently gentrifying tracts

D. Sales in recently non-gentrifying tracts

- Price 7%↓, decaying with distance in non-gentrifying areas

- **Placebo:** re-estimate pop. flows model to identify *ex ante* vs. *ex post* gentrification

▶ *ex ante*: 1990 – 2005

▶ *ex post*: 2005 – 2019

- Insignificant responses in Panels A/B  $\implies$  investors not just amplifying pre-existing trends towards gentrification Definition

- Tax sale investors act as **opportunistic developers**

# EVIDENCE IN FAVOR OF BLIGHT REDUCTION CHANNEL

## A. Most foreclosures (top quartile)

## B. Least foreclosures (below median)

- Consistent with the (+) effects of non-profit rehabs in Ganduri & Maturana (2022)
- Holds even if exclude tax sales involving properties w/mortgage lien

## EVIDENCE ALSO GOES AGAINST STRONG SUPPLY CHANNEL

A. Thinnest markets

B. Thickest markets

- Tax sales might improve very local housing supply by inc. inventory  $\implies P \downarrow$
- Here demand effects (blight reduction + amenities + sorting) dominate supply effects

# NEIGHBORHOOD DEMOGRAPHIC CHANGES THROUGH TAX SALES

## DO TAX SALES DRIVE LOCAL DEMOGRAPHIC CHANGE?

- Two (“push-pull”) forces through which this might happen in SFH market:
  - ▶ **Gentrification:** pos. pricing externalities  $\implies$  neighborhood becomes more inaccessible to lower-income, non-white residents (URM buyer share  $\downarrow$ )
  - ▶ **Displacement:** besides delinquency-related turnover, changing neighborhood demographics/amenities might induce current residents to sell (URM seller share  $\uparrow$ )
    - ★ Mechanisms: property tax hikes (He 2022), homophily (Ihlanfeldt & Scafidi 2002), preferences over amenities (Waldfogel 2008), liquidity constraints (Wong 2020)
- Look at **racial composition** of nearby homeowners imputed from surname  $\times$  location
- Evidence here consistent with gentrification channel Bayes's rule Specification
  - ▶ URM buyer prob. declines by 2 p.p. (relative to a 12% baseline prob.)
  - ▶ But URM seller prob. also declines by 3 p.p. (relative to a 10% baseline prob.)
  - ▶ No consistent patterns around tax sales to individual investors

## ED-STYLE METHOD W/RACE PROBABILITY OUTCOME

- ED method does not converge for areas which are highly segregated (corner solutions)
- Event study with fine distance bins to approximate empirical derivatives method:

$$URM_{i,r,t} = \sum_{k=-3}^{+5} \left\{ \sum_{d=0.05 \text{ mi}}^{0.5 \text{ mi}} \beta_{d,k}^{close,a} \cdot TaxSale\_Close_{i,t,d,k}^a \right. \\ \left. + \sum_{d=0.5 \text{ mi}}^{1 \text{ mi}} \beta_{d,k}^{far,a} \cdot TaxSale\_Far_{i,t,d,k}^a \right\} + \alpha_{r,t} + \gamma_m + \eta' \cdot \mathbf{X}_{i,t} + \nu_{i,r,t} \quad (2)$$

- ▶ e.g.  $TaxSale\_Close_{i,2005,0.1,-1}^a = 1$  if house  $i$  purchased within 0.1 mi. of tax sale property w/title change to investor of type  $a$  in 2006
- ▶  $\alpha_{r,t}$ : ring, block group, or 9-digit zip code  $\times$  year FEs
- ▶ Controls  $\mathbf{X}_{i,t}$ : lat/lon, # bed/baths, floor space, lot size, house age quadratic

# 2% ↓ IN URM BUYER PROB. AFTER TAX SALE FORECLOSURE

CONT. PROB.

IND. RINGS

○ estimated  $\beta_d$     — 95% confidence interval

# URM SELLER PROB. $\downarrow \implies$ MORE WHITE-TO-WHITE SALES

CONT. PROB.

IND. RINGS

Prob. URM Seller

Miles to Property

○ estimated  $\beta_d$     — 95% confidence interval

## POLICY IMPLICATIONS

## RECENTLY CONCLUDED LEGAL BATTLE OVER “HOME EQUITY THEFT”

### ***States Are Not Entitled to Windfalls in Tax Disputes, Supreme Court Rules***

In a unanimous decision, the justices sided with a 94-year-old woman who got nothing when a Minnesota county sold her condominium to recoup unpaid taxes.

The U.S. Supreme Court ruled on Thursday that states cannot retain more than what a taxpayer owed when seizing private property to recoup unpaid taxes. Kenny Holston/The New York Times

Source: [NY Times](#) (May 25, 2023).

- *Tyler v. Hennepin County*: 94 year-old Minnesota widow who had \$40k home seized to pay off \$15k in local tax debts
- Supreme Court unanimously struck down home equity forfeiture under **Fifth Amendment Takings Clause**
- Big implications for property tax reform
  - ▶ 12 states + D.C. have virtually no protections against equity confiscation
  - ▶ In 7 other states (CT, FL, MO, MT, ND, SC, VA), taxpayer still has only a few months to file claim for excess proceeds
- Ongoing issues over “disparate impact”

## WHAT DOES THIS PAPER HAVE TO SAY ABOUT PROPERTY TAX REFORM?

- 1 Valuation of excess proceeds: use *ex ante* prices to the extent that auction process undervalues properties and *ex post* properties may amplify inequality
  - ▶ *Tyler* ruling does not take a stance on what constitutes legally fair value
- 2 Equity-efficiency tradeoffs: disparate impact on certain demographic groups vs. tax sales as a subsidy for CAPX in struggling neighborhoods
- 3 Priority liens: remove super seniority of tax liens in certain situations
- 4 Mental health interventions:
  - ▶ Payments column in ledgers empty in % of cases  $\implies$  not just a liquidity story
  - ▶ **Incidence of Alzheimer's/related dementia (AD/RD) cases plays a role**
- 5 **Financial innovations:** create escrow-mimicking account with opt-in provision that automatically pays taxes, even if no mortgage loan attached
  - ▶ Functions like payroll tax withholding and helps solve delinquency problem

Source: LaPoint et al. (2024): "Losing more than memory: a study of Alzheimer's disease and property tax delinquency to improve human health"

- Strong (+) association of delinquency with future deaths from Alzheimer's Disease & dementias (AD/RD)
- Placebo: not true if look at death rates from acute causes (e.g. heart attacks)
- Missing payments as an indicator of **memory impairment**
- Nationwide database of mortality records linked to CoreLogic
- Precision public health initiatives using publicly available data

# CONCLUSION

- Municipalities hold **tax sales** to recoup lost revenue
  - ▶ Buyer composition strongly tilted towards institutional investors around 2008
  - ▶ **Non-REO intermediaries** target high-value properties in gentrifying areas
- Local price spillover effects: **(−)** on average, but **(+)** in **gentrifying areas**
  - ▶ Investors accelerate demographic trends by redeveloping delinquent properties
  - ▶ Blight reduction: stronger **(+)** effects in areas with more foreclosures
  - ▶ Tax sales amplify within-city racial inequality by crowding out URM buyers
- **Finance-based microfoundation** for gentrification waves within cities
- **Policy: rebate surplus revenues** to delinquent taxpayer instead of the foreclosing entity while (barely) hurting investors' profits → use ex ante price basis

Yale SCHOOL OF MANAGEMENT

THANK YOU!

# APPENDIX

Within-state local property tax delinquency rate

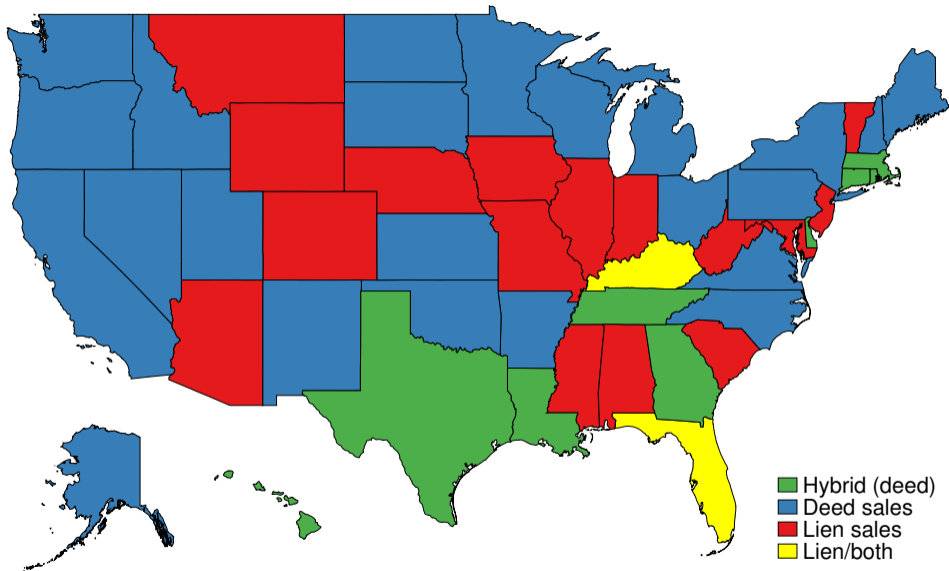

**Notes:** Tabulated using merged CoreLogic Involuntary Liens and Tax data for 2008 – 2014.

- Residualize on state FEs to hold fixed property tax legal regime

- Jurisdictions divided into three types based on how they sell claims:
  - ① Lien sales: interest-bearing certificate with foreclosure option sold at auction or OTC
  - ② Deed sales: local authority – tax or sheriff’s office – directly forecloses and then sells deed at auction or OTC (“special sale”)
  - ③ Hybrid sales: like a deed sale, except redemption period needs to pass before investor can convert deed to title
- No clear political divide in how jurisdictions arbitrate delinquency
- Since redemption periods in deed states can be long, **not much economic distinction between a lien sale and deed sale system**
  - ▶ Difficult for homeowner to redeem in hybrid states because need to pay back both outstanding tax debt + penalties/fees + whatever premium the investor bid  
“credit bid”

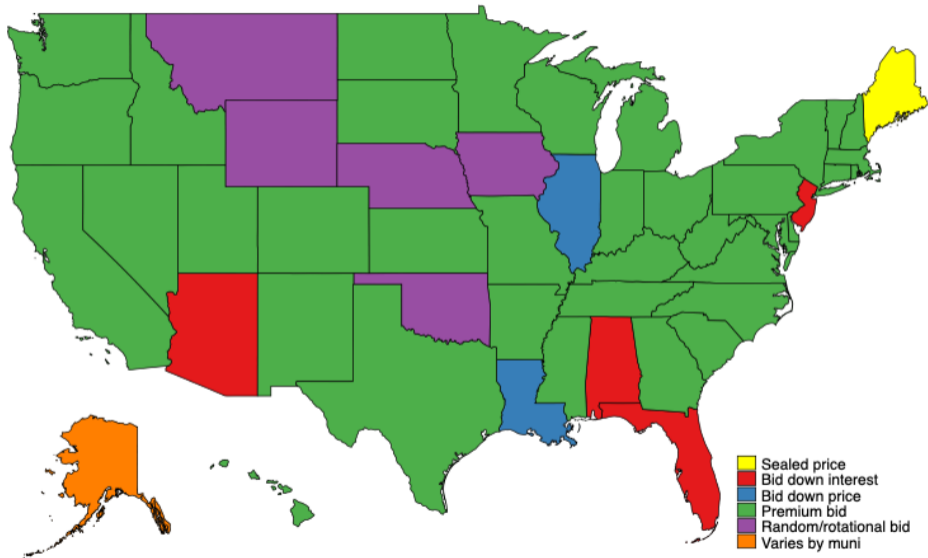

- 1 Local authority sets auction date and lists properties on website for investors to review
  - ▶ This usually happens when the final notice is sent to the taxpayer  $\implies$  properties redeemed at last minute as potential control group
  - ▶ Govt. might also allocate funds to advertise the tax sale
- 2 Almost all tax sales held in person – cancelled in 2020-21 due to COVID
  - ▶ Online sales conducted as sealed price auctions with very little time between lots
- 3 Bidders register with an SSN or EIN for W-9 filing and ownership record
  - ▶ Corporate veil: easy to preserve anonymity, since can create a shell or hire an intern
- 4 Investors place security deposit + fees with clerk prior to placing bids

There are five types of tax auctions, with some limited within-state variation in rules...

- ① Premium bid: investors bid a premium relative to the outstanding tax bill
  - ② Bid down interest: Dutch auction where buyers pay off the tax debt and bid minimum interest they are willing to accept
  - ③ Random/rotational bid: tax authority sets “buy it now” price for each property and bidder numbers randomly called for each lot until someone buys
  - ④ Bid down price: same as bid down interest (IL and LA)
  - ⑤ Sealed first price (Vickrey): currently only in Maine
- Premium bid by far most common method used by 39 out of 51 states
  - Starting bid typically set so the tax authority breaks even

# BIDDING METHODS BY STATE

MAIN DECK

- Extend hybrid option models of Stanton (1995) and Jarrow & Tyagi (2007)
- NPV of a tax lien given foreclosure date  $\chi$  is then the **expected value from the coupons** + **the property's liquidation value in foreclosure less the bid**

$$\begin{aligned}
 NPV_0(\chi) = & \mathbb{E}_Q \left( \underbrace{\mathbb{1}\{0 \leq \tau \leq \chi\} \cdot C \cdot \exp\left(\lambda \cdot \max\{r, i, \tau\} \times \mathbb{1}_A\right)}_{\text{interest coupons to lienholder}} \times \exp\left(-\int_0^\tau r ds\right) \right. \\
 & \left. + \underbrace{\left(\mathbb{1}\{T^* \leq \chi \leq \tau\} \left[ \min\{P_\chi, C \cdot \exp\left(\lambda \cdot \max\{r, i, \chi\} \times \mathbb{1}_A\right)\} - K\right]\right)}_{\text{liquidation value in foreclosure}} \times \exp\left(-\int_0^\chi r ds\right) \right) - \underbrace{C - S}_{\text{total bid}}
 \end{aligned}$$

- Foreclosure date  $\chi$ , where option vests once redemption period of length  $T^*$  passes
- $C$  is the tax debt,  $S$  is surplus, where total bid is  $C + S$

$$\begin{aligned}
 NPV_0(\chi) = & \mathbb{E}_Q \left( \underbrace{\mathbb{1}\{0 \leq \tau \leq \chi\} \cdot C \cdot \exp\left(\lambda \cdot \max\{r, i, \tau\} \times \mathbb{1}_A\right)}_{\text{interest coupons to lienholder}} \times \exp\left(-\int_0^\tau r ds\right) \right. \\
 & \left. + \underbrace{\left( \mathbb{1}\{T^* \leq \chi \leq \tau\} \left[ \min\{P_\chi, C \cdot \exp\left(\lambda \cdot \max\{r, i, \chi\} \times \mathbb{1}_A\right)\} - K \right] \right)}_{\text{liquidation value in foreclosure}} \times \exp\left(-\int_0^\chi r ds\right) \right) - \underbrace{C - S}_{\text{total bid}}
 \end{aligned}$$

- $A = (i \neq 0)$  and indicator  $\mathbb{1}_A$  indicator function for set  $A$
- Delinquent HO picks intensity  $\lambda$  by deciding on redemption time
- Minimum interest rate embedded in tax lien if not redeemed =  $r \times \mathbb{1}_A$
- Exercise foreclosure option whenever  $P_\chi > C + S + K$ 
  - ▶  $K$  is opportunity cost from the PV of (legal) costs incurred over the foreclosure process as of  $\chi$

|                         | Washington, D.C. | Florida           | Massachusetts |
|-------------------------|------------------|-------------------|---------------|
| Sale method             | Lien             | Lien              | Hybrid        |
| Bid method              | Premium bid      | Bid down interest | Premium bid   |
| Redemption period       | 6 months         | 2 years           | 6 months      |
| Maturity/expiration     | 6 months         | 7 years           | 6 months      |
| One-time penalty rate   | 0%               | 5% minimum        | 0%            |
| Annual interest rate    | 12%              | 18%               | 16%           |
| Assumed total bid value | \$16,000         | \$1,000           | \$100,000     |
| Assumed premium bid     | \$2,000          | N/A               | \$75,000      |

- Suppose investor holds each lien until redemption period ends
- Without exercising foreclosure option, guaranteed yields to maturity would be 5.1% on D.C., 18% on FL, and 7.7% on MA lien
  - ▶ Ex: for D.C.,  $(\$16k - \$2k) \times [(1 + 0.0095)^6 - 1] / \$16k = \$816.21 / \$16k = 5.1\%$

- Unconditional value-to-bid (VTB) without adjusting for redemption or collateral risk
  - ▶ Similar discrete spike if adjust for both
  - ▶ Court foreclosure prob. ↓, but quiet foreclosure prob. ↑ over time
- Not solely driven by mortgage foreclosures where bank let the property go
  - ▶ Exclude special OTC auctions
- Even with covariate-adjustment, no decline in VTB over time
- Suggests information asymmetry (Zillow) not driving spreads

$$\text{YTM} = (\text{bid} - \text{surplus}) \times (1 + r)^n / \text{bid}$$

$$\text{YTM} = (\text{bid} - \text{surplus}) \times (1 + r)^n / \text{bid}$$

- Monthly interest rate  $r$  high across all lien states (10% – 20% p.a.)
- Redemption period  $n$  varies from 6 months (MD/D.C.) to 48 months (WY)
- Example: in D.C., YTM maxes out at  $(1 + 0.015)^6 = 9.34\%$
- YTM higher for individual investors
  - ▶ Less likely to compete in contested auctions or file for foreclosure
  - ▶ If condition on surplus  $> 0$ , institutions earn 10 bps. higher YTM

- **Basic idea:** match tax sale properties to loan contracts repoted in CoreLogic...
  - ▶ For D.C. sample, match on address/square combo
- ① Determine main contract features: FRM vs. ARM, origination amount  $C_0$ , quoted rate  $i$ , term  $N$ , payment frequency, etc.
- ② Drop properties matched to a refinancing or second mortgage event
- ③ For FRMs, use standard accounting formulas (see next slide) to obtain  $C_n$  balance, where  $n$  is # months into the loan when tax sale occurs
- ④ For ARMs (< 10% of loans), assume standard contract features consistent with HMDA/FHFA MIRS (e.g. 5/1 loan with 1-year T-bill index)
- ⑤ For remaining loans with  $i$  but missing term and contract type, assume 30-year FRM  $\implies$  overestimate balance  $C_n$

- Loan fully with quoted rate  $i$  amortizes over  $N$  months, so expand the geometric series to obtain monthly payment ( $PMT$ )
- Then iterate on the initial law of motion  $C_1 = (1 + i/12) \times C_0 - PMT$  to find balance after  $n$  months of payments

$$C_0 = \sum_{t=1}^N \frac{PMT}{(1 + i/12)^t} \implies PMT = C_0 \times \left( \frac{i/12}{1 - (1/(1 + i/12))^N} \right)$$

$$C_n = (1 + i/12)^n \times C_0 - \sum_{t=0}^{n-1} (1 + i/12)^t \times PMT$$

$$\implies C_n = (1 + i/12)^n \times C_0 - \frac{PMT \cdot \left( (1 + i/12)^n - 1 \right)}{i/12}$$

# SUMMARY STATISTICS: MOST AUCTION REVENUES FROM SURPLUS BIDS

| Year         | # liens sold  | Back taxes | Interest/penalties | Surplus | Auction revenues | Surplus-revenue ratio (%) | Total tax revenues |
|--------------|---------------|------------|--------------------|---------|------------------|---------------------------|--------------------|
| 2005         | 2,181         | 3.52       | 1.04               | 32.76   | 37.35            | 87.71%                    | 1,136              |
| 2006         | 1,997         | 3.81       | 1.07               | 23.06   | 28.77            | 80.16%                    | 1,212              |
| 2007         | 2,083         | 4.31       | 1.65               | 45.11   | 51.82            | 87.06%                    | 1,542              |
| 2008         | 1,366         | 6.05       | 2.27               | 12.46   | 21.31            | 58.46%                    | 1,727              |
| 2009         | 1,068         | 5.91       | 2.11               | 2.33    | 10.61            | 21.99%                    | 1,839              |

## A. Institutional lien buyers

## B. Individual lien buyers

$$\log B_{i,t} = \delta_t + \gamma_m + \tilde{\alpha}_i + \beta' \cdot \mathbf{X}_{i,t} + \epsilon_{i,t}$$

$$B_t = \exp(\delta_t)$$

$$\log(1 + S_{i,t}) = \delta_t + \gamma_m + \tilde{\alpha}_i + \beta' \cdot \mathbf{X}_{i,t} + \epsilon_{i,t}$$

$$S_t = \exp(\delta_t)$$

- Matching estimator:  $\tilde{\alpha}_i$  address fixed effects (units within same building)
- Idea: surplus bid proxies for tax foreclosure option value because it does not accrue interest

**Notes:**  $\tilde{\alpha}_i$  are address fixed effects. All bid values in real 2012 dollars, converted from nominal terms using the PCE deflator.

## Fraction of Total Amount by Year and Tract Type

Baltimore City

- Abandoned, gentrifying, and LI concentration tracts all over-represented relative to all arms-length, non-tax deed transactions
- But gentrifying tracts are 5x over-represented**
- On a scale from D.C. to Detroit, cities like Indy which experienced bad subprime foreclosure crisis generally fall in the middle

Source: Detroit Open Data Portal for 2012–2019.

- 85% of tax deed sales occur in low-income concentration/abandoned areas, many involving realty companies and non-profits

- **Real estate data**

- ▶ Proprietary databases: CoreLogic Tax/Deeds/Involuntary Liens, Zillow ZTRAX
- ▶ Tax sale records: FOIA requested and scraped from local tax authorities when possible
- ▶ Merge tax sale addresses to CoreLogic whenever possible to retrieve lat/lon, otherwise use Google Maps API → determine ring positions

- **Business entry/exit and amenities**

- ▶ ArcGIS Business Analyst (Shoag & Veuger 2018) + DnB/NETS database
- ▶ Yelp public-use dataset for high frequency nowcasting

- **Census data**

- ▶ IPUMS-NHGIS extracts from decennial Census and ACS on neighborhood demographics
- ▶ State and local govt. finance data (ASSLGF + STC)

|                                 | Pre-recession (2005-08) | Foreclosure crisis (2009-12) | Recovery (2013-19) | Total         |
|---------------------------------|-------------------------|------------------------------|--------------------|---------------|
| Institutional + gentrifying     | 2,253                   | 2,337                        | 1,408              | 5,998         |
| Individual + gentrifying        | 1,153                   | 574                          | 640                | 2,367         |
| Institutional + non-gentrifying | 2,118                   | 2,375                        | 1,748              | 6,241         |
| Individual + non-gentrifying    | 1,525                   | 650                          | 859                | 3,304         |
| <b>Total</b>                    | <b>7,049</b>            | <b>5,936</b>                 | <b>4,655</b>       | <b>17,640</b> |

**Source:** D.C. Office of Tax & Revenue Buyer's Books (2005-2019). Tabulations exclude sales to non-profit buyers, or 4.2% of the sample (779 liens).

- Around each tax sale event, draw three rings and compute avg. price for properties within radius  $r$  miles:  $R^{in}(r \leq 0.1)$ ,  $R^{mid}(0.1 < r \leq 0.5)$ ,  $R^{out}(0.5 < r \leq 1)$
- Then two sets of treatment effects by year:

$$Inner\_treatment(T) = (R_{\ell,T}^{in} - R_{\ell,T}^{out}) - (R_{\ell,-1}^{in} - R_{\ell,-1}^{out}) \quad (3)$$

$$Middle\_treatment(T) = (R_{\ell,T}^{mid} - R_{\ell,T}^{out}) - (R_{\ell,-1}^{mid} - R_{\ell,-1}^{out}) \quad (4)$$

- ▶ Differences between rings in  $T$  are relative to one year before the tax sale event in  $T = 0$
  - ▶ Bin estimates at  $t = -5$  and  $t = +10$  to separate dynamic effects from secular time trends
- Importantly, this method only takes out the year FEs, but not local time trends

- Prices pre-trend up (down) in (non-)gentrifying areas
- True for both middle and inner ring estimates
- Similar result if split rings by initial assessed value
- In gentrifying areas, inner ring estimates (+) drop off after around 0.5 mi.
  - ▶ No gradient w.r.t. distance in non-gentrifying areas (-)

Main deck

- Split middle rings by quartile of tax assessed value as of year prior to sample
- Tax assessed value from Zillow ZTRAX (CoreLogic doesn't go back that far)
- Similar trends to ring estimates split by gentrifying vs. non-gentrifying
- Additional evidence that tract type model based on flows picks up prices (revealed preference)

Main deck

**Notes:** Each estimate compares average prices of homes sold in the inner ring within 0.1 miles of a tax sale property relative to an outer ring of properties 0.5 to 1 miles away, and pre vs. post-tax sale event. Unit prices winsorized at the 1st and 99th percentiles. 95% confidence intervals obtained via 1,000 block bootstrap iterations at the tax sale ring level.

- Starting with  $N = 18,419$  D.C. tax lien sales, merge to CoreLogic and track subsequent title transfers beyond the 6 month redemption period
  - ▶ → 8,693 of which have title changes after the redemption date
  - ▶ → of these, 5,448 exchanged in arms-length transactions
  - ▶ → of these, 2,146 transferred to institutional owner (event definition)
  - ▶ → overall, only 14 exchanges to the mortgage lender
- Similar proportions if exclude repeat delinquencies, or use auction date as event cutoff
  - ▶ → 868 transfers to institutional owners out of 4,368 title changes
  - ▶ Repeat delinquencies are a way for LLCs to retain the corporate veil
- $\implies$  foreclosure rate conditional on tax lien sale is  $868/8,693 \approx 10\%$

# HETEROGENEITY BY NEIGHBORHOOD TYPE (INDIVIDUAL BUYERS)

MAIN DECK

A. Sales in previously gentrifying tracts

B. Sales in previously non-gentrifying tracts

C. Sales in recently gentrifying tracts

D. Sales in recently non-gentrifying tracts

- Similar effects in gentrifying areas for individual buyers
- **Placebo:** re-estimate pop. flows model to identify *ex ante* vs. *ex post* gentrification
  - ▶ *ex ante*: 1990 – 2005
  - ▶ *ex post*: 2005 – 2019
- Insignificant, non-monotonic responses in Panels A/B  $\implies$  investors not just amplifying pre-existing trends
- Non-monotonic responses in non-gentrifying areas, but no statistical significance

## Pricing Effects of Tax Sales on Nearby Properties in Recently Gentrifying Tracts

Main deck

| Distance (mi.) →     | 0.05                  | 0.1                   | 0.15                  | 0.2                   | 0.25                  | 0.3                   | 0.35                  | 0.4                   | 0.45                  | 0.5                   |

- House prices around tax sale property  $S$  follow:

$$\log(p_{i,t}) = m_S(d_i, \tau_i) + \phi_S(d_i, \theta_i) + \gamma_S(\theta_i, t_i) + \varepsilon_{i,t} \quad (5)$$

- ▶  $i$  relates to  $S$  in polar coordinate plane  $(d, \theta)$
  - ▶  $\tau_i$  number of years since the tax sale transfer
  - ▶  $\phi_S(\cdot)$  and  $\gamma_S(\cdot)$  allow house prices to vary across locations and trend differently across time in multiple directions
  - ▶  $m_S(\cdot)$  is the two-dimensional empirical derivative of interest
- Find partial derivative of  $p_{i,t}$  w.r.t.  $d$ , holding  $\theta_i$  and  $t_i$  fixed, by computing:

$$\frac{\log(p_{d-\delta, \theta, t}) - \log p_{d+\delta, \theta, t}}{2\delta}, \quad \text{for } \delta > 0$$

- Iteratively compare properties  $d - \delta$  and  $d + \delta$  from  $S$  to difference out the local effects (take a bunch of diff-in-diff pairs)

- The empirical derivatives estimator is semi-parametric in that researchers must still choose six tuning parameters:
  - ❶  $h_{r,n}$ : smoothing in distance (miles)
  - ❷  $h_{t,n}$ : smoothing in time (years)
  - ❸  $g_n^t$  bowtie search area width in time
  - ❹  $g_n^\theta$  bowtie search area width in polar distance
  - ❺  $\kappa_n$ : max # of house price pairs included in bowtie
  - ❻  $r$ : ring radius within which to trace out the derivative
- Compared to two other papers using this method, I use smaller  $r$  and  $h_{r,n}$ 
  - ▶ Tax sales more numerous and geographically clustered
  - ▶ Results largely robust to choices of tuning parameters

## Alternative Tuning Parameters for Empirical Derivatives Estimator

- Use `wru` R package developed by Imai & Khanna [IK] (2016)
  - ▶ Infer racial category  $\mathcal{R}$  using location  $\ell$  and surname  $\mathcal{S}$  in Census surname list
- Then estimate  $\tilde{p} \equiv \Pr(R_i = \mathcal{R} | L_i = \ell, S_i = \mathcal{S})$  via Bayes's rule
  - ▶ Assumes location and surname statistically independent conditional on race, or  $L_i \perp\!\!\!\perp S_i | R_i$
- Try three definitions of racial category probability
  - 1 Set  $URM = 1$  if  $\tilde{p} > 0.5$  for Black or Hispanic
  - 2 Set  $URM = 1$  if highest probability race is Black or Hispanic (exactly follows IK)
  - 3 Continuous Bayesian probability that race is either Black or Hispanic

High correlation with L2 voter registration data at block group level

- “Other” includes surnames with majority Native American, multi-racial respondents, and any rare surnames not in the Census surname list

# ALSO NOT MUCH EFFECT ON URM SELLER PROB. FOR IND. TAX LIENS

○ estimated  $\beta_d$     — 95% confidence interval

## TWO-STAGE GENTRIFICATION MODEL

- Deep question debated in sociology since the 1980s
- Two main strands of sociological models taken to data:
  - ① **“Stage” models** (Marcuse 1985, 1986): **layered sort** of geographic areas into four categories
    - ★ **Abandonment**, **gentrification**, **growth**, **low income concentration**
  - ② Risk aversion models (Gale 1979; Kerstein 1990): persistence of gentrification depends on migrants’ risk attitudes towards amenity preservation
- Contrast to the urban economics literature which tries to model **within-metro sorting** through **utility maximization problems**
  - ▶ Brueckner & Rosenthal (2009); Guerrieri, Hartley, Hurst (2013); Lee & Lin (2018); Couture & Handbury (2019); Murphy (2021); Su (2022)
  - ▶ **Econ state variables often used as factor sorts in the sociological stage models**

- Generalization of stage model adopted by UMN Institute on Metropolitan Opportunity
  - ▶ I generalize and apply the model to all U.S. Census tracts over 1990–2005 and 2005–2019
- Intuition for each sorting stage:
  - ① **1st stage:** sort areas based on strength of local economy (i.e. in-migration)
  - ② **2nd stage:** further sort based on ability to accommodate low-income pop. growth
- High/low income population shares form a **sufficient statistic** for local economic performance as in standard  $V = Z \cdot W/P^\beta$  sorting condition
  - ▶ Few assumptions, but results consistent with more complicated sorts (e.g. housing prices)
- Use of thresholds reminiscent of Schelling's (1971, 1978) **tipping point theory**

## MODEL COMPLETELY GOVERNED BY THREE THRESHOLD PARAMETERS

- Model characterized by a vector  $\mathbf{x} := \{x_1, x_2, x_3\}$ 
  - ▶  $x_1$  [1st stage]: % change in non-low-income residents
  - ▶  $x_2$  [1st stage]: p.p. change in low-income population share
  - ▶  $x_3$  [2nd stage]: % change in low-income residents
- **Robustness:** check how maps change as I iterate over values in  $\mathbf{x}$ 
  - ▶ Baseline: select  $x_1, x_2$  to match avg. tipping points observed within metro area
  - ▶ Exercise complements race-based RD-style tests in Bayer, Fang, & McMillan (2014)
- Examine neighborhood “persistence” under two definitions:
  - ▶ *Type persistence*: prob. tract type is exactly the same in subperiod  $t$  and  $t + 1$
  - ▶ *Gentrification persistence*: correlation of dummy for weak/strong gentrifying (under  $\underline{\mathbf{x}}$  vs.  $\bar{\mathbf{x}}$ ) between  $t$  and  $t + 1 \rightarrow \text{corr} \approx 0 \implies$  long-run steady state

## TRANSITION MATRIX: GENTRIFICATION RARELY FOLLOWED BY REVERSALS

|                         | <i>Abandonment</i> | <i>Gentrification</i> | <i>Growth</i> | <i>LI Concentration</i> | <i>Unclassified</i> |
|-------------------------|--------------------|-----------------------|---------------|-------------------------|---------------------|
| <i>Abandonment</i>      | <b>0.47%</b>       | 0.58%                 | 0.15%         | 0.13%                   | 2.02%               |
| <i>Gentrification</i>   | 0.37%              | <b>2.33%</b>          | 0.75%         | 1.46%                   | 4.48%               |
| <i>Growth</i>           | 0.17%              | 0.79%                 | <b>0.64%</b>  | 0.54%                   | 2.51%               |
| <i>LI Concentration</i> | 0.53%              | 1.52%                 | 0.033%        | <b>6.95%</b>            | 6.45%               |
| <i>Unclassified</i>     | 1.59%              | 9.69%                 | 3.43%         | 14.18%                  | <b>36.76%</b>       |

**Notes:** Rows indicate the initial tract type in 1990-2005, while columns indicate the more recent tract type in 2005-2019.

- 1/4 of initially *gentrifying* continue to gentrify, while 48% reach the steady state represented by *unclassified*
- Only 19% of *gentrifying* tracts reverse course to become *abandoned* or *LIC*

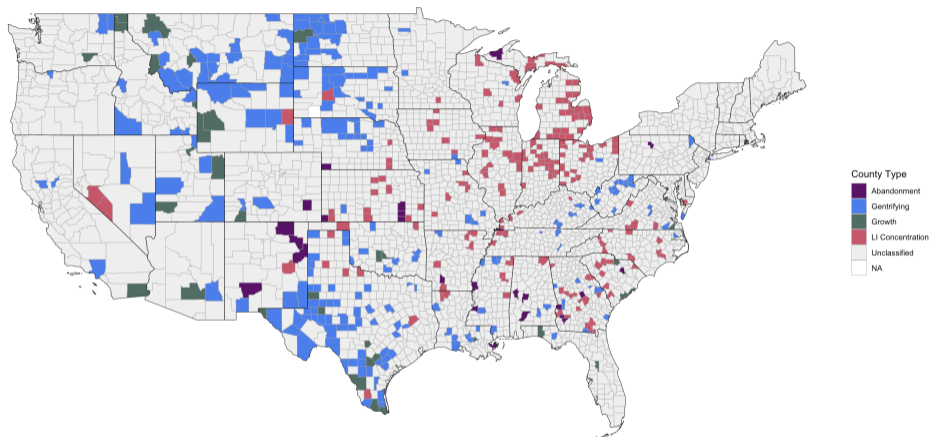

- Standard procedures following Opportunity Atlas of Chetty et al. (2018)
- Convert variable  $X_{j,t}$  between 2000 tract  $j$  and 2010 tract  $k$  via:

$$X_{k,t} = \sum_{j \subseteq k} \omega_j \cdot X_{j,t}$$

$$\omega_j = \frac{\text{2010 population of overlap}}{\text{2010 population of the 2000 tract}}$$

- Map 1990 tracts to 2010 using similar procedure: first reweight from 1990 to 2000 geography, then reweight to go from 2000 to 2010
- Can also aggregate from block group level but more missing values

- Using “strong” cutoff parameters  $\{\bar{x}_1, \bar{x}_2, \bar{x}_3\} = \{10\%, 5\text{p.p.}, 0\%\}$ , where unclassified means demographic change is sufficiently minimal

- Using “weak” cutoff parameters  $\{\underline{x}_1, \underline{x}_2, \underline{x}_3\} = \{5\%, 2.5\text{p.p.}, 0\%\}$  and lumping weak and strong types together

- Tract type probabilities all decreasing with respect to  $x_1$  and  $x_2$  first stage thresholds
  - ▶ More stringent definition of neighborhood change  $\implies$  more tracts unclassified
- Abandonment/gentrification move in opposite direction of LIC/growth w.r.t.  $x_3$  since former are about low-income population decline
- In practice, pick parameters to match tipping points observed for each metro area
